WEEK NINE

Glycogen

Animals store excess glucose by polymerizing it to form **glycogen**. The structure of glycogen is similar to that of amylopectin, although the branches in glycogen tend to be shorter and more frequent. Glycogen is broken back down into glucose when energy is needed (a process called glycogenolysis). The liver and skeletal muscle are major depots of glycogen.

Structural Polysaccharides

plants use different **polysaccharides**, such as cellulose, for structural purposes in their cell walls. The exoskeleton of many arthropods and mollusks is composed of chitin, a **polysaccharide** of N-acetyl-D-glucosamine.

Cellulose

Cellulose is probably the single most abundant organic molecule in the biosphere. It is the major structural material of which plants are made. Wood is largely cellulose and lignin while cotton and paper are almost pure cellulose. Cellulose is derived from D-glucose units, which <u>condense</u> through $\beta(1\rightarrow 4)$ -glycosidic bonds. Cellulose is a straight chain polymer: unlike starch, no coiling or branching occur Cellulose is a polymer made with repeated glucose units bonded together by *beta*-linkages. Humans and many other animals lack an enzyme to break the beta-linkages, so they do not digest cellulose. Certain animals can digest cellulose, because bacteria possessing the enzyme cellulose are present in the gut. Classical examples are ruminant and termites.

Hemicellulose

<u>Hemicellulose</u> is a polysaccharide related to cellulose that comprises ca. 20% of the biomass of most plants. In contrast to cellulose, hemicellulose is derived from several sugars in addition to glucose, including especially <u>xylose</u> but also <u>mannose</u>, <u>galactose</u>, <u>rhamnose</u>, and <u>arabinose</u>. Hemicellulose consists of shorter chains - around 200 sugar units. Furthermore, hemicellulose is branched, whereas cellulose is unbranched.

Chitin

is a homopolymer of N-acetyl-D-glucosamine, with units joined by beta 1-> 4 bonds. Chitin is found in organisms as diverse as algae, fungi, insects, arthropods, mollusks, and insects. Chitin is a long-chain <u>polymer</u> of a <u>N-acetylglucosamine</u>, a derivative of glucose, and is found in many places throughout the natural world. It is the main component of the <u>cell walls</u> of <u>fungi</u>, the <u>exoskeletons</u> of <u>arthropods</u> such as <u>crustaceans</u> (e.g. <u>crabs</u>, <u>lobsters</u> and <u>shrimps</u>) and <u>insects</u>, the <u>radulas</u> of <u>mollusks</u> and the beaks of <u>cephalopods</u>, including <u>squid</u> and <u>octopuses</u>. Chitin has also proven useful for several medical and industrial purposes. Chitin may be compared to the polysaccharide <u>cellulose</u> and to the protein <u>keratin</u>. Although keratin is a protein, and not a <u>carbohydrate</u> like chitin, keratin and chitin have similar structural functions.

Uses

Agriculture

Most recent studies point out that chitin is a good inducer for <u>defense mechanisms</u> in plants.^[4] It was recently tested as a <u>fertilizer</u> that can help plants develop healthy <u>immune</u> responses, and have a much better yield and life expectancy.^[5] The <u>Chitosan</u> is derived from chitin, which is used as a <u>biocontrol</u> elicitor in <u>agriculture</u> and <u>horticulture</u>.

Industrial

Chitin is used industrially in many processes. It is used in <u>water purification</u>, and as an additive to thicken and stabilize foods and <u>pharmaceuticals</u>. It also acts as a binder in <u>dyes</u>, <u>fabrics</u>, and <u>adhesives</u>. Industrial <u>separation membranes</u> and <u>ion-exchange resins</u> can be made from chitin. Processes to <u>size</u> and strengthen <u>paper</u> employ chitin.

Medicine

Chitin's properties as a flexible and <u>strong</u> material make it favorable as <u>surgical thread</u>. Its <u>bio-degradibility</u> means it wears away with time as the wound heals. Moreover, chitin has some unusual properties that accelerate healing of wounds in humans.^[7].
