

# **PHS 211 LECTURE NOTES**

## **CLASSICAL PHYSICS**

By Olasunkanmi Isaac OLUSOLA (Ph.D.)

### **Course contents**

An introduction to classical mechanics, space and time, straight line kinematics, motion in a plane; forces and conservation particle dynamics, collisions and conservation laws, work and potential energy, inertia forces and non-inertia frames; central focus motions, rigid bodies and rotational dynamics.

### **Suggested references:**

1. Classical mechanics by Golstein, published by McGrawhill
2. Fundamentals of Physics by J. Walker
3. A shorter intermediate mechanics by D. Humphrey
4. A textbook of dynamics by F. Chorton, published by Ellis Horwood Ltd.

## 1.0 INTRODUCTION TO CLASSICAL MECHANICS

Mechanics is the study of the effects of external forces on bodies at rest or in motion. Such bodies could be rigid or elastic (solids), liquids or gases. The quantitative concepts used in mechanics can be classified into two groups:

- (1) The FUNDAMENTAL CONCEPTS – consisting of length, mass & time and
- (2) The DERIVED CONCEPTS which include other terms such as density, area and speed.

By understanding classical mechanics, a student prepares himself to pursue the fields of space physics, relativistic mechanics, statistical mechanics, acoustics, elasticity and fluid mechanics all of which can be traced to Newton, laws of motion.

Mechanics play a far wider role in physical sciences. Classical mechanics is other wisely termed Newton in mechanics.

### THE CLASSICAL MODELS OF TIME & SPACE

In the Newtonian (classical) models, intervals of time are modeled by real numbers and these real numbers are measured by instruments known as clocks. The real number which models a given interval of time will depend on the unit of time used to calibrate the clocks. The SI unit of time is second.

### SCALAR & VECTOR

Quantities with magnitudes only are called scalars while these with both magnitude and direction are referred to as vectors.

Notation of vectors

In 1 – dim.  $\mathbf{x} = x\mathbf{x}$

Where  $\mathbf{x} = 1\mathbf{x}$  and  $\mathbf{x}$  is a unit vector in  $x$  – direction i.e. along  $x$  – axis.

In 3 – dim  $\mathbf{r} = (x, y, z)$  in Cartesian coordinate

$(r, \theta, \phi)$  in spherical polar coordinate

$(r, \theta, z)$

$\mathbf{V} = \lambda \mathbf{v}$  where  $\lambda$  is a scalar quantity

In parallel, then  $\mathbf{v} = \lambda \mathbf{V}$ ,  $\lambda = \text{scalar}$

## ADDITION OF VECTORS

If  $r_1$  and  $r_2$  are two vectors, then

$$\mathbf{r} = \mathbf{r}_1 + \mathbf{r}_2 = \mathbf{r}_2 + \mathbf{r}_1 \quad \text{commutative law is obeyed under addition of vectors}$$

If  $r_1$  and  $r_2$  are inclined at angle  $\beta$ , then cosine rule can be applied to determine the resultant vector  $\mathbf{r}$  as

$$\mathbf{r} = r_1^2 + r_2^2 - 2r_1 r_2 \cos \beta$$

## COMPONENT OF A VECTOR

$F = (F_x, F_y)$  in cartesian coordinate syst.

$$F_x = F \cos \theta$$

$$F_y = F \sin \theta$$

In plane polars

$$F = (F, \theta)$$

In 3 – dim

$$F = (F_x, F_y, F_z) \text{ in cartesian coordinate system}$$

$$F = (F, \theta, \phi) \text{ in spherical polars}$$

Where

$$F_x = F \sin \theta \cos \phi$$

$$F_y = F \sin \theta \sin \phi$$

$$F_z = F \cos \theta$$

$di$  = volume element

$$= dx dy dz \text{ in ordinary space of the Cartesian coordinate system}$$

$$= r^2 \sin \theta dr d\theta d\phi \text{ i.e. volume element in ordinary space in spherical polars.}$$

## VECTOR NOTATIONS

$\mathbf{i}$  = unit vector along x-direction

$$= \mathbf{v}_x$$

$\mathbf{j}$  = a unit vector along y-direction

$$= \mathbf{v}_y$$

$$\mathbf{V} = v \cos \theta \mathbf{i} - v \sin \theta \mathbf{j}$$

$$\mathbf{V} = (V_x, V_y, V_z) = (V_{xi} + V_{yj} + V_{zk})$$

## Direction cosine

If the vector  $\mathbf{v}$  makes an angle  $\lambda$  with x-axis,  $\beta$  with y-axis & and angle  $\gamma$  z-axis, then

$$V_x/v = \cos \lambda$$

$$V_y/v = \cos \beta$$

$$V_z/v = \cos \gamma$$

Since  $\cos^2 \lambda + \cos^2 \beta + \cos^2 \gamma = 1$ , then the angle which various components make the respective direction is called the direction cosine.

## ADDITION OF SEVERAL VECTORS

$$\mathbf{r} = \mathbf{r}_1 + \mathbf{r}_2 + \mathbf{r}_3 + \dots\dots\dots$$

$$= (r_1x + r_2x + r_3x + \dots) \mathbf{i} + (r_1y + r_2y + r_3y + \dots) \mathbf{j} +$$

## SCALAR OR DOT PRODUCT

If there are two vectors  $\mathbf{m}$  and  $\mathbf{n}$ , then  $\mathbf{m} \cdot \mathbf{n} = mn \cos \theta = \mathbf{n} \cdot \mathbf{m}$  i.e. dot product is commutative

Where  $m = |\mathbf{m}|$  and  $n = |\mathbf{n}|$

Properties of dot product

(1.) If  $\mathbf{k}$  is another vector, the dot product is distributive with respect to.  $\mathbf{k}$  i.e.

$$\mathbf{k} \cdot (\mathbf{m} + \mathbf{n}) = \mathbf{k} \cdot \mathbf{m} + \mathbf{k} \cdot \mathbf{n}$$

(2.) Dot product is commutative

$$\mathbf{m} \cdot \mathbf{n} = \mathbf{n} \cdot \mathbf{m}$$

## VECTOR PRODUCT

Vector product of  $\mathbf{m}$  and  $\mathbf{n}$  is defined as

$$\mathbf{m} \times \mathbf{n} = (mn \sin \theta) \mathbf{k}$$

$$\text{If } \mathbf{m} = (m_x, m_y, m_z)$$

$$\mathbf{n} = (n_x, n_y, n_z)$$

$$\text{Then, } \mathbf{m} \times \mathbf{n} = (m_y n_z - m_z n_y) \mathbf{i} - (m_x n_z - m_z n_x) \mathbf{j} + (m_x n_y - m_y n_x) \mathbf{k}$$

## Properties

- (1) In vector product: order of multiplication is important i.e.  $\mathbf{m} \times \mathbf{n} + \mathbf{n} \times \mathbf{m}$  hence it is non-commutative
- (2) It is distributive i.e.  $\mathbf{k} \times (\mathbf{m} + \mathbf{n}) = \mathbf{k} \times \mathbf{m} + \mathbf{k} \times \mathbf{n}$

## KINEMATICS

Mechanics deals with relations of force, matter and motion. The branch of mechanics that describes motion without reference to force is "Kinematics". Rest and motion are relative, therefore, we need a frame of reference.

Rectilinear motion i.e. motion in a straight line

Average velocity between points A and B is denoted by  $V$ , which is defined

$$U = \frac{x_1 - x_0}{t_1 - t_0} = \frac{\Delta x}{\Delta t} \dots \dots \dots (1)$$

Instantaneous velocity i.e. velocity at a particular time

$$V = \lim_{\Delta t \rightarrow 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt} \dots \dots \dots (2)$$

In general,  $V$  depends on time i.e.  $V$  is a function of time i.e.

$$V = V(t)$$

Then:

$$dx = V(t) dt$$

$$\int_{x_0}^{x_1} dx = \int_{t_0}^{t_1} v(t) dt$$

$$[x(t)]_{x_0}^{x_1} = \int_{t_0}^{t_1} v(t) dt$$

$$\Rightarrow x(t) - x(t_0) = \int_{t_0}^{t_1} V(t) dt$$

x is measured in metres, t in sees and V in ms<sup>-1</sup>.

Example: Suppose  $x(t) = (at^2 + C) \frac{m}{s^2}$  where a & c are constants.

$$V(t) = \frac{dx}{dt} = (2at) \frac{m}{s}$$

$$V = \frac{\Delta x}{\Delta t}$$

$$= \frac{x(t) - x(t_0)}{t - t_0} \frac{m}{s}$$

$$= \frac{a(t^2 - t_0^2)}{t - t_0} \frac{m}{s}$$

$$= \frac{a(t - t_0)(t + t_0)}{t - t_0} \frac{m}{s}$$

$$= a(t + t_0) \frac{m}{s}$$

Acceleration: Uniform acceleration  $\Rightarrow V \neq V(t)$

In general, however, V depends on time i.e.  $V = V(t)$

$$\bar{a} = \frac{V(t) - V(t_0)}{t - t_0} = \frac{\Delta v}{\Delta t} \dots\dots\dots (3)$$

$$a = a(t) = \lim \frac{\Delta v}{\Delta t} = \frac{dv}{dt} \dots\dots\dots (4)$$

$$\Delta t \rightarrow 0 \quad dt$$

If  $a \neq a(t)$ , then it is uniform acceleration. If  $V$  increases as  $t$  increases, then we have acceleration but if  $V$  decreases as  $t$  increases, then it is deceleration or retardation.

$$a(t) = \frac{dv(t)}{dt}$$

$$a = \frac{dv}{dt} = \frac{d}{dt} \left( \frac{dx}{dt} \right) = \frac{d^2x}{dt^2} \dots\dots\dots (5)$$

$$\Rightarrow \int_{v_0}^v dv(t) = \int_{t_0}^t a(t) dt$$

$$\text{i.e. } V(t) - V(t_0) = \int_{t_0}^t a(t) dt$$

Recall from (4) and (2) that

$$dv(t) = a(t)dt \dots\dots\dots(a)$$

$$v(t) = \frac{dx(t)}{dt} \dots\dots\dots(b)$$

$$\Rightarrow v(t) dv(t) = a(t) dt \cdot \frac{dx(t)}{dt} \dots\dots\dots(6)$$

$$\Rightarrow V \cdot dv = a \cdot dx$$

$$\int_{v_0}^v V dv = \int a \cdot dx$$

$$\Rightarrow \frac{1}{2} [v^2]_{v_0} = \int a \cdot dx$$

Hence, knowing  $a(x)$  r. h. s can be calculated, the acceleration,  $a$ , is measured in  $\text{ms}^{-2}$ .
